## PRE LAB QUESTION \& ANSWERS

1. What is microprocessor?
2. What is the function of program counter?
3. What is the function of stack pointer?
4. What is an operating system?
5. What is the function of $A L E$, and $S 0, S 1$ pin?

## 1. STUDY OF 8051 MICROCONTROLLER

Aim
To study the microcontroller 8051
Architecture of 8051 Microcontroller

Architecture of 8051 microcontroller has following features

- 4 Kb of ROM is not much at all.
- 128 Kb of RAM (including SFRs) satisfies the user's basic needs.
- 4 ports having in total of 32 input/output lines are in most cases sufficient to make all necessary connections to peripheral environment.

The whole configuration is obviously thought of as to satisfy the needs of most programmers working on development of automation devices. One of its advantages is that nothing is missing and nothing is too much. In other words, it is created exactly in accordance to the average user's taste and needs. Other advantages are RAM organization, the operation of Central Processor Unit (CPU) and ports which completely use all recourses and enable further upgrade.

## Pin out Description

Pins 1-8: Port 1 each of these pins can be configured as an input or an output.
Pin 9: RS A logic one on this pin disables the microcontroller and clears the contents of most registers. In other words, the positive voltage on this pin resets the microcontroller. By applying logic zero to this pin, the program starts execution from the beginning.

Pins10-17: Port 3 Similar to port 1, each of these pins can serve as general input or output. Besides, all of them have alternative functions:

Pin 10: RXD Serial asynchronous communication input or Serial synchronous communication output.

Pin 11: TXD Serial asynchronous communication output or Serial synchronous communication clock output.

Pin 12: INT0 Interrupt 0 inputs.
Pin 13: INT1 Interrupt 1 input.
Pin 14: T0 Counter 0 clock input.
Pin 15: T1 Counter 1 clock input.
Pin 16: WR Write to external (additional) RAM.
Pin 17: RD Read from external RAM.

Pin 18, 19: X2, X1 Internal oscillator input and output. A quartz crystal which specifies operating frequency is usually connected to these pins. Instead of it, miniature ceramics resonators can also be used for frequency stability. Later versions of microcontrollers operate at a frequency of 0 Hz up to over 50 Hz .

## Pin 20: GND Ground.

Pin 21-28: Port 2 If there is no intention to use external memory then these port pins are configured as general inputs/outputs. In case external memory is used, the higher address byte, i.e. addresses A8-A15 will appear on this port. Even though memory with capacity of 64 Kb is not used, which means that not all eight port bits are used for its addressing, the rest of them are not available as inputs/outputs.

Pin 29: PSEN If external ROM is used for storing program then a logic zero (0) appears on it every time the microcontroller reads a byte from memory.

Pin 30: ALE Prior to reading from external memory, the microcontroller puts the lower address byte (A0-A7) on P0 and activates the ALE output. After receiving signal from the ALE pin, the external register (usually 74 HCT 373 or 74 HCT 375 add-on chip) memorizes the state of P0 and uses it as a memory chip address. Immediately after that, the ALU pin is returned its previous logic state and P0 is now used as a Data Bus. As seen, port data multiplexing is performed by means of only one additional (and cheap) integrated circuit. In other words, this port is used for both data and address transmission.

Pin 31: EA By applying logic zero to this pin, P2 and P3 are used for data and address transmission with no regard to whether there is internal memory or not. It means that even there is a program written to the microcontroller, it will not be executed. Instead, the program written to external ROM will be executed. By applying logic one to the EA pin, the microcontroller will use both memories, first internal then external (if exists).

Pin 32-39: Port 0 Similar to P2, if external memory is not used, these pins can be used as general inputs/outputs. Otherwise, P0 is configured as address output (A0-A7) when the ALE pin is driven high (1) or as data output (Data Bus) when the ALE pin is driven low (0).

Pin 40: VCC +5 V power supply.

## Input/Output Ports (I/O Ports)

All 8051 microcontrollers have 4 I/O ports each comprising 8 bits which can be configured as inputs or outputs. Accordingly, in total of 32 input/output pins enabling the microcontroller to be connected to peripheral devices are available for use.

Pin configuration, i.e. whether it is to be configured as an input (1) or an output (0), depends on its logic state. In order to configure a microcontroller pin as an input, it is necessary to apply a logic zero ( 0 ) to appropriate I/O port bit. In this case, voltage level on appropriate pin will be 0 .

Similarly, in order to configure a microcontroller pin as an input, it is necessary to apply a logic one (1) to appropriate port. In this case, voltage level on appropriate pin will be 5 V (as
is the case with any TTL input). This may seem confusing but don't loose your patience. It all becomes clear after studying simple electronic circuits connected to an I/O pin.

## Memory Organization

The 8051 has two types of memory and these are Program Memory and Data Memory. Program Memory (ROM) is used to permanently save the program being executed, while Data Memory (RAM) is used for temporarily storing data and intermediate results created and used during the operation of the microcontroller. Depending on the model in use (we are still talking about the 8051 microcontroller family in general) at most a few Kb of ROM and 128 or 256 bytes of RAM is used. However...

All 8051 microcontrollers have a 16-bit addressing bus and are capable of addressing 64 kb memory. It is neither a mistake nor a big ambition of engineers who were working on basic core development. It is a matter of smart memory organization which makes these microcontrollers a real "programmers' goody".

## Special Function Registers (SFRs)

Special Function Registers (SFRs) are a sort of control table used for running and monitoring the operation of the microcontroller. Each of these registers as well as each bit they include, has its name, address in the scope of RAM and precisely defined purpose such as timer control, interrupt control, serial communication control etc. Even though there are 128 memory locations intended to be occupied by them, the basic core, shared by all types of 8051 microcontrollers, has only 21 such registers. Rest of locations is intentionally left
unoccupied in order to enable the manufacturers to further develop microcontrollers keeping them compatible with the previous versions. It also enables programs written a long time ago for microcontrollers which are out of production now to be used today.

## Program Status Word (PSW) Register

PSW register is one of the most important SFRs. It contains several status bits that reflect the current state of the CPU. Besides, this register contains Carry bit, Auxiliary Carry, two register bank select bits, Overflow flag, parity bit and user-definable status flag.
$\mathbf{P}$ - Parity bit. If a number stored in the accumulator is even then this bit will be automatically set (1), otherwise it will be cleared (0). It is mainly used during data transmit and receive via serial communication.

- Bit 1. This bit is intended to be used in the future versions of microcontrollers.

OV Overflow occurs when the result of an arithmetical operation is larger than 255 and cannot be stored in one register. Overflow condition causes the OV bit to be set (1). Otherwise, it will be cleared (0).

RS0, RS1 - Register bank select bits. These two bits are used to select one of four register banks of RAM. By setting and clearing these bits, registers R0-R7 are stored in one of four banks of RAM.

| RS1 | RS2 | Space in RAM |
| :---: | :---: | :--- |
| 0 | 0 | Bank0 00h-07h |
| 0 | 1 | Bank1 08h-0Fh |
| 1 | 0 | Bank2 10h-17h |
| 1 | 1 | Bank3 18h-1Fh |

F0 - Flag 0. This is a general-purpose bit available for use.
AC - Auxiliary Carry Flag is used for BCD operations only.
CY - Carry Flag is the (ninth) auxiliary bit used for all arithmetical operations and shift instructions.

## Data Pointer Register (DPTR)

DPTR register is not a true one because it doesn't physically exist. It consists of two separate registers: DPH (Data Pointer High) and (Data Pointer Low). For this reason it may be treated as a 16 -bit register or as two independent 8 -bit registers. Their 16 bits are primarly used for external memory addressing. Besides, the DPTR Register is usually used for storing data and intermediate results.

## Stack Pointer (SP) Register

A value stored in the Stack Pointer points to the first free stack address and permits stack availability. Stack pushes increment the value in the Stack Pointer by 1 . Likewise, stack pops decrement its value by 1 . Upon any reset and power-on, the value 7 is stored in the Stack Pointer, which means that the space of RAM reserved for the stack starts at this location. If another value is written to this register, the entire Stack is moved to the new memory location.

## P0, P1, P2, P3 - Input/Output Registers

| 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | |  | P0.7 | P0.6 | P0.5 | P0.4 | P0.3 |
| :---: | :---: | :---: | :---: | :---: | :---: |

Value after Reset Bit name

If neither external memory nor serial communication system are used then 4 ports with in total of 32 input/output pins are available for connection to peripheral environment. Each bit within these ports affects the state and performance of appropriate pin of the microcontroller. Thus, bit logic state is reflected on appropriate pin as a voltage ( 0 or 5 V ) and vice versa, voltage on a pin reflects the state of appropriate port bit.

As mentioned, port bit state affects performance of port pins, i.e. whether they will be configured as inputs or outputs. If a bit is cleared (0), the appropriate pin will be configured as an output, while if it is set (1), the appropriate pin will be configured as an input. Upon reset and power-on, all port bits are set (1), which means that all appropriate pins will be configured as inputs.

## Counters and Timers

As you already know, the microcontroller oscillator uses quartz crystal for its operation. As the frequency of this oscillator is precisely defined and very stable, pulses it generates are always of the same width, which makes them ideal for time measurement. Such crystals are also used in quartz watches. In order to measure time between two events it is sufficient to count up pulses coming from this oscillator. That is exactly what the timer does. If the timer is properly programmed, the value stored in its register will be incremented (or decremented) with each coming pulse, i.e. once per each machine cycle. A single machine-cycle instruction lasts for 12 quartz oscillator periods, which means that by embedding quartz with oscillator frequency of 12 MHz , a number stored in the timer register will be changed million times per second, i.e. each microsecond.

The 8051 microcontroller has 2 timers/counters called T0 and T1. As their names suggest, their main purpose is to measure time and count external events. Besides, they can be used for generating clock pulses to be used in serial communication, so called Baud Rate.

## Timer T0

As seen in figure below, the timer T0 consists of two registers - TH0 and TL0 representing a low and a high byte of one 16 -digit binary number.

Accordingly, if the content of the timer T 0 is equal to $0(\mathrm{~T} 0=0)$ then both registers it consists of will contain 0 . If the timer contains for example number 1000 (decimal), then the TH0 register (high byte) will contain the number 3, while the TL0 register (low byte) will contain decimal number 232.

Formula used to calculate values in these two registers is very simple:
TH0 $\times 256+\mathrm{TL} 0=\mathrm{T}$
Matching the previous example it would be as follows:
$3 \times 256+232=1000$

Since the timer T0 is virtually 16 -bit register, the largest value it can store is 65535 . In case of exceeding this value, the timer will be automatically cleared and counting starts from 0. This condition is called an overflow. Two registers TMOD and TCON are closely connected to this timer and control its operation.

## TMOD Register (Timer Mode)

The TMOD register selects the operational mode of the timers T0 and T1. As seen in figure below, the low 4 bits (bit0 - bit3) refer to the timer 0 , while the high 4 bits (bit4-bit7) refer to the timer 1. There are 4 operational modes and each of them is described herein.

Bits of this register have the following function:

- GATE1 enables and disables Timer 1 by means of a signal brought to the INT1 pin (P3.3):
- $\mathbf{1}$ - Timer 1 operates only if the INT1 bit is set.
- $\mathbf{0}$ - Timer 1 operates regardless of the logic state of the INT1 bit.
- $\mathbf{C} / \mathbf{T} 1$ selects pulses to be counted up by the timer/counter 1:
- $\mathbf{1}$ - Timer counts pulses brought to the T1 pin (P3.5).
- $\mathbf{0}$ - Timer counts pulses from internal oscillator.
- T1M1,T1M0 These two bits select the operational mode of the Timer 1.

| T1M1 | T1M0 | Mode | Description |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 13-bit timer |
| 0 | 1 | 1 | 16-bit timer |
| 1 | 0 | 2 | 8-bit auto- <br> reload |
| 1 | 1 | 3 | Split mode |

- GATE0 enables and disables Timer 1 using a signal brought to the INT0 pin (P3.2):
- $\mathbf{1}$ - Timer 0 operates only if the INT0 bit is set.
- $\mathbf{0}$ - Timer 0 operates regardless of the logic state of the INT0 bit.
- $\mathbf{C / T 0}$ selects pulses to be counted up by the timer/counter 0:
- $\mathbf{1}$ - Timer counts pulses brought to the T0 pin (P3.4).
- $\mathbf{0}$ - Timer counts pulses from internal oscillator.
- T0M1,T0M0 These two bits select the oprtaional mode of the Timer 0 .

| T0M1 | T0M0 | Mode | Description |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 13-bit timer |
| 0 | 1 | 1 | 16-bit timer |
| 1 | 0 | 2 | 8-bit auto-reload |
| 1 | 1 | 3 | Split mode |

## Timer Control (TCON) Register

TCON register is also one of the registers whose bits are directly in control of timer operation.
Only 4 bits of this register are used for this purpose, while rest of them is used for interrupt control to be discussed later.

- TF1 bit is automatically set on the Timer 1 overflow.
- TR1 bit enables the Timer 1.
- $\mathbf{1}$ - Timer 1 is enabled.
- $\mathbf{0}$ - Timer 1 is disabled.
- TF0 bit is automatically set on the Timer 0 overflow.
- TR0 bit enables the timer 0 .
- $\mathbf{1}$ - Timer 0 is enabled.
- $\mathbf{0}$ - Timer 0 is disabled.

## Timer 1

Timer 1 is identical to timer 0 , except for mode 3 which is a hold-count mode. It means that they have the same function, their operation is controlled by the same registers TMOD and TCON and both of them can operate in one out of 4 different modes.

## Result:

Thus the 8051 Architecture has been studied.

## POST LAB QUESTION \& ANSWERS

1. What are the advantages of an assembly language in comparison with high level language?
2. What is the function of HOLD and HLDA signal?
3. What is the function of TRAP, RST7.5, RST6.5, RST5.5 interrupt?
4. What is the function of timing and control unit?
5. What is the function of SID and SOD pin?

DEPT. OF ELECTRICAL \& ELECTRONICS ENGINEERING SRM INSTITUTE OF SCIENCE AND TECHNOLOGY, Kattankulathur - 603203.

## PRE-LAB

1. Specify the number of registers in a 2 K memory chip?
2. What is an assembler?
3. What are the advantages of an assembly language in comparison with high level language?
4. List the components of computer?
5. What is an operating system?

## 2. ARTHMETIC OPERATIONS USING 8051

## Aim:

To do the arithmetic operations using 8051 microprocessor

## Apparatus required:

8085 microprocessor kit
DAC interface kit
Keyboard

## Algorithm:

## Addition / Subtraction

Step 1 :
Step $2 \quad: \quad$ Add or subtract $1^{\mathrm{H}}$ data with $2^{\text {nd }}$ data
Step 3 : Initialize data pointer.
Step $4 \quad: \quad$ Move result to memory pointed by DPTR.

## Multiplication / Division

Step $1: \quad$ Get $1^{\mathrm{H}}$ data and $2^{\text {nd }}$ data to memory
Step $2 \quad: \quad$ Multiply or divide $1^{\mathrm{H}}$ data with $2^{\text {nd }}$ data
Step 3 : Initialize data pointer.
Step $4 \quad: \quad$ Move result to memory pointed by DPTR (first port)
Step 5 : Increment DPTR
Step $6 \quad: \quad$ Move $2^{\text {nd }}$ part of result to register A
Step $7 \quad: \quad$ Move result to $2^{\text {nd }}$ memory location pointer by DPTR

## Program: 8-bit Addition:

| Memory <br> Location | Label | Opcode | Mnemonics | Comments |
| :---: | :---: | :---: | :--- | :--- |
| 4100 |  | 7401 | MOV A, \#01 | Moves data 1 to <br> register A |
| 4102 |  | 2402 | ADD A, \#02 | Add content of A and <br> data 2 and store in A |
| 4104 |  | 904500 | MOV DPTR,\#4500 | Moves data 4500 to <br> DPTR |
| 4107 |  | F0 | MOVX @ DPTR,A | Moves control of A to <br> location pointed DTPR |
| 4108 |  | 80 FE | SJMP 4108 | Short jump to 4108 |

| :---: | :---: |
| 4500 |  |

## Result:

Thus 8-bit addition, subtraction, multiplication and division is performed using 8051.

## POST-LAB

6. Define OPCODE and Operand, and specify the opcode and the operand in the instruction MOV H, L.
7. Find the machine codes and the number of bytes of for the following instructions. Identify the opcode and the operands.
a) MVI $\mathrm{H}, 47 \mathrm{H}$
b) ADI F5H
c) SUB C
8. Find the HEX codes for the following instructions, identify the opcodes and operands, and show the order of entering the codes in memory

STA 2050H
JNZ 2070H
9. Classification of 8085 Instruction set.
10.Find the hex machine code for the following instruction from the instruction set and identify the number of bytes of each instruction and assume that the starting address is 2000 H .

MVI B, 45 H
MVI C, 78 H
MOV A,C
ADD B
OUT 07H
HLT.

## 3.FINDING MAXIMUM VALUE IN AN ARRAY

## PRE-LAB

1. What is a bus?
2. How many address lines are necessary to address 2048 K memory?
3. Why is the data bus bidirectional?
4. Why are the program counter and Data Pointer 16 bit registers?
5. What is a transparent latch, why it is necessary to use a latch with output devices such as LEDs?

## 3.FINDING MAXIMUM VALUE IN AN ARRAY

## Aim:

Write an assembly language program to find the biggest number in an array of 8-bit unsigned numbers of predetermined length.

## Apparatus required:

8051 microcontroller kit (0-5V) DC battery

## Algorithm:

1. Initialize pointer and counter.
2. Load internal memory location 40 H as zero.
3. Move the first element of an array to 55 register.
4. Compare the data stored in memory location 40 H is equal to or less than the value of first element of an array.
5. If it is lesser, then move the data of first element to 40 H memory location ELSE increment pointer and decrement counter.
6. Check the counter. If counter is not equal to zero, repeat from the $2{ }^{\text {nd }}$ step else Move the R5 register to 40H memory location.
7. Stop the program.

Program:

| Memory <br> Location | Label | Opcode | Mnemonics | Comments |
| :--- | :---: | :---: | :--- | :--- |
| 4100 |  | 904200 | MOV DPTR,\#4200H |  |
| 4103 |  | 754000 | MOV 40H,\#00H |  |
| 4106 |  | 7D 0A | MOV R5,\#05H | Give the number of inputs for <br> finding the largest number. |

## OUTPUT:

| Memory address | Data |
| :---: | :---: |
|  |  |

## RESULT:

Thus the assembly language program was written to find the largest element in an array and executed using 8051 microcontroller.

## POST-LAB

1. Draw the pin diagram of 8051 microcontroller?
2. Write some applications of microcontroller.
3. Explain the operation of MOVX @DPTR, A, MOVX A, @DPTR and MOV DPTR, \#DATA16 instructions?
4. Define DPTR.
5. What is use of EA pin?

DEPT. OF ELECTRICAL \& ELECTRONICS ENGINEERING SRM INSTITUTE OF SCIENCE AND TECHNOLOGY, Kattankulathur - 603203.

## 4. SORTING OF DATA-ASCENDING ORDER-DESCEDING

## PRE-LAB

1. Mention any four addressing modes of 8051 ?
2. Mention the timers of 8051 ?
3. Mention the SFR registers used in timer operation?
4. Mention the operating modes of 8051 ?
5. What is RS 232C?

## 4. SORTING OF DATA-ASCENDING ORDER-DESCEDING

## AIM:

To arrange an array of 8-bit unsigned numbers of known length in an ascending order.

## Apparatus required:

8051 microcontroller kit
(0-5V) DC battery

## Algorithm:

1. Initialize the register and data pointer.
2. Get first two elements in registers $\mathrm{A} \& B$.
3. Compare the two elements of data. If value of $B$ register is high then exchange $A$ \& B data else increment pointer and decrement register R3.
4. Check R3 is zero, and then move the register R5 \& R6.
5. Again increment pointer and decrement R 4 ,
6. Check R4 is zero. If no repeat the process from step 2.
7. Otherwise stop the program.

# 5. HEXTO ASCII CONVERSION 

## PRE-LAB

## 1. What is T -state?

2. Define opcode and operand.
3. What is meant by memory mapping?
4. What is Vectored and Non- Vectored interrupt?
5. What is Polling ? What are the different types of Polling?

## 5. HEX TO ASCII CONVERSION

Aim:
Write an assembly language program to convert a HEX to its equivalent ASCII code and display the result in the address field.

## Apparatus required:

8051 microcontroller kit
(0-5V) DC battery

## Algorithm:

1. Get the ASCII characters in the range 0 to 9 or A to F as input
2. Compare whether it falls in the range 0 to 9 or A to F
3. If it falls in the range 0 to 9 add 30 H or add 37 H
4. Display the result in the address field.

## Program:

Hint: 0 to 9 in ASCII equivalent Hex value is 30 H to 39 H and for A to F in ASCII is 41H to 46 H

| Memory <br> Location | Label | Opcode | Mnemonics | Comments |
| :---: | :---: | :---: | :---: | :---: |
| 4100 |  | 904200 | MOV DPTR,\#4200H | Input a HEX Value |
| 4103 |  | E0 | MOVX A, @DPTR |  |
| 4104 |  | F8 | MOV R0,A |  |
| 4105 |  | 940 A | SUBB A, \#0AH | Compare Value 0-9 |

| 4109 |  | 2430 | ADD A,\#30H |  |
| 410 A |  | 8003 | SJMP LOOP | 0-9 Add 30H |
| 410 C |  | E8 | MOV A, R0 |  |
| 410 E | LOOP 1 | 2437 | ADD A, \#37H | A-F Add 37H |
| 410 F |  | 904500 | MOV DPTR, \#4500H |  |
| 4111 | LOOP | F0 | MOVX @DPTR, A | Output Hex Value Equivalent to <br> ASCII Character |
| 4114 |  | 80 FE | SJMP 4115 |  |
| 4115 |  |  |  |  |

## SAMPLE INPUT AND OUTPUT:

## INPUT:

| Memory address | Data |
| :--- | :--- |
| 4200 | Hex $=$ |

## OUTPUT:

| Memory address | Data |
| :---: | :--- |
| 4500 | ASCII equivalent Hex <br> Value $=$ |

## Result:

Thus the assembly language program was written to convert HEX to ASCII and executed using 8051 microcontroller.

## POST LAB

1. Which program produces the .obj file?
2. Show the lowest and highest values (in hex) that the 8051 program counter can take.
3. What is PUSH and POP instruction? Give example.
4. What is the difference between SJMP, LJMP and AJMP?
5. What are the addressing modes of 8051 ?

DEPT. OF ELECTRICAL \& ELECTRONICS ENGINEERING SRM INSTITUTE OF SCIENCE AND TECHNOLOGY, Kattankulathur - 603203.

## 6. FIND THE SQUARE ROOT OF A GIVEN DATA PRE-LAB

1. What is the purpose of EA, PSEN and ALE in 8051 ?
2. How many ports are there in 8051 and by default the ports are set as output/input port?
3. Which ports of 8051 are bit-addressable?
4. Give any five Special Function Registers.
5. What is the advantage of register indirect addressing?

## 6. FIND THE SQUARE ROOT OF A GIVEN DATA

## Aim:

To write an assembly language program to find the square root of a given data

## Apparatus required:

8051 microcontroller kit
(0-5V) DC battery

## Algorithm:

1. Enter a program.
2. Enter the input hex value to location 4200 h .
3. Execute the program.
4. The output square root value stored in a location 4500h.

PROGRAM:

| Memory Location | Label | Opcode | Mnemonics | Comments |
| :---: | :---: | :---: | :---: | :---: |
| 4100 | Origin: | 904200 | MOV DPTR,\#4200h | Get a input data |
| 4103 |  | E0 | MOVX A,@DPTR |  |
| 4104 |  | F9 | MOV R1,a |  |
| 4105 |  | 7A 01 | MOV R2, \#01h | Initialize counter |
| 4107 | L1: | E9 | MOV A,R1 |  |
| 4108 |  | 8A F0 | MOV B,R2 |  |
| 410a |  | 84 | DIV AB | divide the given value and counter |

|  |  |  |
|  |  |  |

## Result:

Thus an assembly language program displaying characters on seven segment display has been executed.

## POST-LAB

1. Name some bit addressable register?
2. How the baud rate can doubled?

## 3. What is TI and RI interrupts?

4. What are the rotate instructions which involve with carry?
5. What is the function of SWAP instruction?

DEPT. OF ELECTRICAL \& ELECTRONICS ENGINEERING SRM INSTITUTE OF SCIENCE AND TECHNOLOGY, Kattankulathur - 603203.

## PRE LAB QUESTION AND ANSWERS

1. Explain the various steps involved when executing CALL instruction.
2. What is the use of PUSH and POP instruction?
3. What is a subroutine program?

## 9. Eight-Bit Digital to Analog Converter

## Aim:

To write an assembly language program to display Characters on a seven display interface.

## Apparatus required:

8051 microcontroller kit
(0-5V) DC battery

## Algorithm:

1. Move the Port Address of DAC 2 FFC8 to the DPTR.
2. Move the Value of Register A to DPTR and then Call the delay.
3. Move the Value of Register A (FFh) to DPTR and the call the dalay.
4. Repeat the steps 2 and 3.

## PROGRAM TO GENERATE SQUARE WAVEFORM

| Memory <br> Location | Label | Opcode | Mnemonics | Comments |
| :---: | :---: | :---: | :---: | :---: |

## PRE LAB QUESTION AND ANSWERS

1. What is NV-RAM?
2. What is the use of PUSH and POP instruction?
3. What is a subroutine program?

## 10. Eight-Bit Analog to Digital Converter

## Aim:

To write an assembly language program to display Characters on a seven display interface.

## Apparatus required:

8051 microcontroller kit
(0-5V) DC battery

## Algorithm:

1. Make ALE low/high by moving the respective data from A register to DPTR.
2. Move the SOC( Start Of Conversion) data to DPTR from FFD0
3. Check for the End Of Conversion and read data from Buffer at address FFC0
4. End the Program.

## PROGRAM:

Port Address for 74LS174 Latch: FFC8
Port Address for SOC: FFD0
Port Address for EOC 1: FFD8
Port Address for 74LS 244 Buffer: FFC0

| Memory <br> Location | Label | Opcode | Mnemonics | Comments |
| :---: | :---: | :---: | :---: | :---: |

## PRE LAB QUESTION AND ANSWERS

1. What is an interrupt?
2. Define Polling.
3. What is the disadvantage of polling?

## 11. Internal Interrupt

## Aim:

To write an assembly language program for Internal Interrupt.

## Apparatus required:

8051 microcontroller kit
(0-5V) DC battery

## Algorithm:

1. Move the value 081 H to the Interrupt Enable pin to enable it.
2. Press INT0 interrupt is enabled. LED's are on.
3. End the Program.

## PROGRAM:

| Memory <br> Location | Label | Opcode | Mnemonics | Comments |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 4100 |  | 758910 | MOV TMOD, \#10H | TIMER 1 MODE 1 |  |

## PRE LAB QUESTION AND ANSWERS

1. What is stepper motor?
2. Define Step angle.
3. What are the applications of stepper motor?

## 12. SPEED CONTROL OF STEPPER MOTOR

Aim:
To write an assembly program to make the stepper motor run in forward and reverse direction.

## Apparatus required:

Stepper motor
8051 microprocessor kit
( $0-5 \mathrm{~V}$ ) power supply

## Algorithm:

1. Fix the DPTR with the Latch Chip address FFC0
2. Move the values of register A one by one with some delay based on the 2-

Phase switching Scheme and repeat the loop.
3. For Anti Clockwise direction repeat the step 3 by reversing the value sequence.
4. End the Program
